The President’s Malaria Initiative (PMI) Africa Indoor Residual Spraying (AIRS) Project conducted pyrethrum spray catch (PSC) and human landing catch (HLC) activities in the Democratic Republic of Congo (DRC) in 11 sentinel sites in 2017. The project conducted PSC and HLC during three periods: January to February, March to April, and May to June in nine sentinel sites. Of the 11 sites, four are new locations conducting trapping activities for the first time. The project monitored malaria vector dynamics and behavior monthly from January to December 2017 in two sites, Kapolowe and Lodja. \textit{Anopheles gambiae} s.l. was present in all 11 sites, but were collected in higher numbers in Kabondo, Kalemie, Karawa, Pawa, and Lodja. The project captured another major malaria vector, \textit{An. funestus} s.l., at higher densities in Katana, Mikalayi, Kabondo, and Kimpese.

The project completed insecticide susceptibility bioassays using \textit{Anopheles gambiae} s.l. for permethrin, deltamethrin, and alpha-cypermethrin in 11 sites, with intensity tests in 10 sites. The team documented resistance to permethrin at all sites, to deltamethrin in four sites, and to alpha-cypermethrin in two sites. Resistance intensity to permethrin was high in all sites. Resistance intensity to deltamethrin was generally lower, with 98-100% mortality at 10 times the diagnostic concentration in five sentinel sites.

The project conducted Centers for Disease Control and Prevention (CDC) bottle bioassays in March, June, and July to determine the intensity of resistance in the Kinshasa suburbs in the wake of the 2016 mass long-lasting insecticide-treated net (LLIN) distribution campaign. In all Kinshasa municipalities, \textit{An. gambiae} s.l. were susceptible to 5X and 10X the diagnostic concentration of deltamethrin. In contrast, there were survivors to permethrin at 2X, 5X, and 10X the diagnostic concentration. There did not appear to be any clear
differences between 2016 and 2017 resistance intensity, with no clear increase in resistance intensity as a result of LLIN distribution.

The University of Notre Dame (UND) has sequenced a sub-sample of *An. paludis* as part of a wider effort to determine malaria risk after recording high biting rates in some sites. Of the *An. paludis* samples tested from Kapolowe, the majority were molecularly identified as being *coustani*-like species (*An. cf coustani* 1 & 2) with the sequences corresponding to those previously reported from Zambia. The team conducted HLC in Kenge in the Kwango Province to collect specimens of *An. paludis*, which Karch and Mouchet identified in 1992 as a malaria vector in this region [1].

As part of the capacity building component, the team, in collaboration with the National Malaria Control Program (NMCP), conducted a group training for three supervisors from each of the 11 sites in Kinshasa from July 17 to July 22, 2017.
1. INTRODUCTION

Morbidity and mortality due to malaria remain a serious public health problem in the Democratic Republic of Congo (DRC) despite sustained malaria control strategies. According to the 2013/14 Demographic and Health Survey (DHS), from a total of 7,250 dried blood spots tested from children sampled across all 26 Provincial Health Divisions/Divisions Provinciales de la Santé (DPS), Rapid diagnostic tests produced a 30.9% positive rate for \textit{P. falciparum} using while polymerase chain reaction (PCR) produced a 34.1% rate. Current malaria control strategies in DRC rely heavily on core vector control interventions, especially the use of long lasting insecticide nets (LLINs). WHO estimates that between 2014 and 2016, approximately 61 million LLINs were distributed, with 77% of the population having access to an LLIN according to modelling studies (WHO, 2016). Between 2010 and 2014, LLINs aided by therapeutic treatments contributed to a 10% reduction of malaria morbidity and a 37% reduction in deaths for children under five years old (PSN, 2016-2020). However, more recent data indicated a trend showing an estimated increase of 500,000 malaria cases between 2015 and 2016 (WHO, 2016), which may in part be due to improvements in the reporting system and increased utilization of health services.

LLIN mass distribution campaigns are organized with the support of donors, including the President’s Malaria Initiative (PMI), and occur throughout many DRC regions. The NMCP has planned LLIN distributions every three years since 2007, with mass distribution campaigns taking place annually in different provinces. In 2017, mass distribution campaigns were conducted with Yorkool\textsuperscript{®}, Duranet\textsuperscript{®} and Dawaplus 2.0\textsuperscript{®}. In addition to mass distributions, Permanet 2.0\textsuperscript{®} and Duranet\textsuperscript{®} are distributed to pregnant women during antenatal care visits and to children under one year of age at health clinics. Abt
Associates conducts entomological monitoring and surveillance through PMI’s Africa Indoor Residual Spraying (AIRS) Project in the DRC to help evaluate the impact of LLIN use on malaria vectors (vector density, seasonal distribution, behavior, species composition, and insecticide susceptibility). This report covers the entomological activities Abt undertook in 11 sites (Kingasani, Kalemie, Katana, Mikalayi, Lodja, Kapolowe, Kabondo, Pawa, Karawa, Inongo, and Kimpese) during year three of the task order (TO6) contract.

2. **PROJECT OBJECTIVES**

The goal of entomological activities in the DRC is to build capacity in generating data on malaria vectors and to develop tools to control them. The objectives are to:

1. Continue to conduct high-quality entomological monitoring activities with minimum technical assistance from outside the DRC.

2. Expand support for monitoring species composition, seasonality, behavior, and infectivity of malaria vectors in 11 sentinel sites (previously seven) in 11 provinces: Kinshasa, Kasai, Sankuru, Tshopo, Haut-Uele, Sud Kivu, Haut Katanga, Tanganyika, Kongo Central, Mai-Ndombe, and Sud Ubangi.

3. Determine the susceptibility level of the main vector of malaria, *Anopheles gambiae* s.l., to three insecticides (permethrin, deltamethrin and alpha-cypermethrin) recommended by the World Health Organization (WHO) Pesticide Evaluation Scheme for LLINs in the 11 sentinel sites. We also will determine the intensity of insecticide resistance to permethrin and deltamethrin using the CDC bottle assay in seven sites.

4. Continue to support the evaluation of *Anopheles paludis* as a malaria vector in Kapolowe (Haut Katanga) and Lodja (Sankuru). This includes close collaboration with the UND for sequencing mosquito samples to determine
whether An. paludis is a species complex with some species being more important malaria vectors.

5. Determine the impact of insecticide resistance on mosquito survival following exposure to LLINs using WHO cone bioassays for permethrin and deltamethrin LLINs with both insectary-reared susceptible and wild resistant An. gambiae s.l. mosquitoes.

6. Provide technical and material assistance to the NMCP in the development of its indoor residual spraying (IRS) strategy and national resistance monitoring plan.

7. Hire an AIRS medical entomologist who will provide daily support to the National Institute of Bio-medical Research/Institut National de Recherche Biomédicale (INRB) team on all technical and administrative matters.

8. Continue to build entomological capacity by strengthening laboratory quality assurance through collaboration with the UND and conducting training in mosquito identification with support from the new medical entomologist.
3. Methodology

3.1. Study Area

The project undertook entomological monitoring activities in 11 sentinel sites (Kingasani, Kalemie, Katana, Mikalayi, Lodja, Kabondo, Kapolowe, Pawa, Karawa, Inongo and Kimpese) in the DRC (Figure 1 and Table 1) in 2017.

INRB staff based in Kinshasa traveled to each site in 2017 to provide technical support. Sampling periods were January-March, April-June, and July-September in 9 of 11 sites. Vector sampling frequency in Kapolowe and Lodja was conducted monthly to determine seasonal vector dynamics.

In Lodja, monthly sampling was conducted in the following sites:

- **Cotonnière**: altitude 414m, **S 03° 32’ 369”**, **E 023° 34’ 981”** (Jan, May, June, July, Aug, Sept, Oct, Nov, Dec).
- **Diengenga**: altitude, 494m, **S 03° 26’ 613”**, **E 023° 36’ 301”** (February)
- **Asami (Edingo)**: altitude 453m, **S 03° 30’ 948”**, **E 023° 35’ 716”** (March)
- **Shapembe**: altitude 461m, **S 03° 32’ 092”**, **E 023° 37’ 617”** (April)

In Kapolowe, monthly mosquito sampling was conducted in several locations within Kapolowe Mission.

**Kapolowe Mission**: altitude 1145 m, **S 10° 56’ 655”**, **E 026° 57’ 014”**

### 3.2. Insecticide Susceptibility and Resistance Intensity Monitoring

Collections of *Anopheles gambiae* s.l. larvae were performed in all 11 sentinel sites using larval dippers and sieves. The larvae were reared in a field insectary and the emergent adults were raised to two to five days old for insecticide resistance tests. Insecticide resistance status was assessed using the WHO cylinder test using diagnostic concentrations of deltamethrin (0.05%), permethrin (0.75%), and alpha-cypermethrin (0.05%). At least 100 *An. gambiae* s.l. were exposed to each insecticide in replicates of 25. The project monitored knock-down every 10 minutes for 60 minutes. The tested mosquitoes were then transferred to a clean paper cup, provided with cotton wool soaked in sugar solution, and mortality was scored 24 hours after exposure.
The project determined the intensity of insecticide resistance to deltamethrin and permethrin using the CDC bottle assay for the first time in seven sentinel sites. Four replicates of 20 An. gambiae s.l. were exposed to each concentration of one, two, five, and 10 times the diagnostic dose. Following CDC protocols, the team recorded mortality at the diagnostic time of 30 minutes.

3.3. Human Biting Rate

Human Landing Catch (HLC)

The project used the HLC method to assess mosquito biting times and feeding behavior and to monitor species composition and sporozoite rates. Two teams collected adult mosquitoes during four consecutive nights (in two different houses each night), with one person indoors and the other outdoors in each selected house. Four collectors worked at each house, with each person working a six-hour shift (one person from 18:00 to midnight and the other from midnight to 06:00 indoors and outdoors). The human biting rate (HBR) was calculated for each sampling period based on eight person nights of collection.

3.4. Indoor resting densities

Pyrethrum Spray Catch (PSC)

The project used PSC to estimate the indoor resting density of mosquito species. Indoor PSC was used in ten houses/bedrooms at each sentinel site. The PSCs were carried out between 06:00 and 10:00. All occupants were asked to move water, food, or anything that insecticide could harm out of the house before spraying. The project sprayed a commercial aerosol (Baygon, SC Johnson, South Africa) containing the pyrethroids imiprothrin, prallethrin, tetramethrin, and synergist piperonyl butoxide (PBO) in each room; white sheets were lined on floors and other surfaces to collect mosquitoes. All mosquitoes were collected from the white sheets 15 minutes after spraying.
Female *Anopheles* mosquitoes were classified according to abdominal status (unfed, fed, half-gravid, or gravid). Each mosquito was labeled for subsequent analysis at INRB for sibling species identification using PCR and other lab-based analysis.

### 3.5. Testing the effect of resistance on LLIN-induced mortality using cone bioassays

Pyrethroid nets containing permethrin, deltamethrin, and alphacypermethrin were collected from Inongo in the province of Mai-Ndombe. Net age was estimated based on the timing of previous distribution campaigns in the region. Four of each of the following LLINs were collected from the community:

1. Permethrin LLIN (Olyset®): 5 years old
2. Deltamethrin LLIN (Yorkool®): 1 year old
3. Alpha-cypermethrin LLIN (Duranet®): 6 months old

Four nets of each brand were tested using WHO cone bioassays. Each net was tested with five cones, with one cone placed on each of the four sides at different heights, and one in the center of the roof. Bioassays were conducted with both insectary reared susceptible *An. gambiae* Kisumu and wild pyrethroid resistant *An. gambiae* s.l from Kingasani (Kinshasa) to determine the impact of resistance on survival following exposure to LLINs.

The efficacy of the used nets was compared with new nets of each brand obtained from Centre de Recherche Entomologique de Cotonou (CREC), Benin in October 2017, with mortality compared with the WHO bio-efficacy threshold.

### 3.6. Impact of mass distribution of LLINs on the intensity of insecticide resistance in Kinshasa

The objective of this study was to determine if selection pressure due to mass distribution of LLINs affects insecticide resistance intensity in Kinshasa. Insecticide resistance intensity in *Anopheles gambiae* s.l. was monitored in four
sites (Bu, Kingasani, Kinkole, and Kimpoko) within Kinshasa before the start of the 2016 mass LLIN distribution campaign. Resistance was monitored using the intensity assay (bottle bioassays using 1, 2, 5, and 10 times the diagnostic dose of permethrin and deltamethrin). Insecticide resistance intensity was also monitored in Kasangulu, a control area 40km from Kinshasa where there was no plan for mass distribution of LLINs (the last distribution in Kasangulu was in 2014). Intensity assays were conducted in 2017 in March, June, and October.

4. Results

4.1. Vector Susceptibility to Insecticides

Maps of resistance for permethrin, deltamethrin, and alpha-cypermethrin are shown in Figure 2. Detailed results and comparison with 2016 data are shown in Table 2. There was no mortality for control bioassays conducted with oil-treated blank papers in 2017 (Table 2).

Permethrin resistance was widespread in DRC. The team recorded it at all 11 sentinel sites at moderate or high frequency (Figure 2). In Katana and Kapolowe, the frequency of permethrin resistance increased, with 38% (95% CI: 29-48) and 9% (95% CI: 5-16) mortality in 2017, compared with 100% at both sites in 2016 (Table 2); however, for Kapolowe it should be noted that resistance to permethrin was previously recorded in 2015.

The project observed deltamethrin resistance in four sites (Kimpese, Karawa, Pawa, and Kalemie) and detected possible resistance in five sites (Kingasani, Mikalayi, Kabondo, Kapolowe, and Lodja). The *An. gambiae* s.l. populations from Inongo and Katana were susceptible to deltamethrin 0.05%.
Populations of *An. gambiae* s.l. were fully susceptible to alpha-cypermethrin (0.05%) in all sites except Kingasani and Kalemie, where the project detected resistance. There was also possible resistance in Karawa.

**Notes:**
- **(S)** = susceptibility
- **(R)** = resistance
- **(PR)** = possible resistance
Resistance intensity data for permethrin and deltamethrin for seven sentinel sites are summarized in Tables 3 and 4. In all seven sites, *An. gambiae* s.l. were highly resistant to permethrin, with relatively low mortality even at 10 times the diagnostic concentration.

Resistance intensity to deltamethrin was generally lower than to permethrin, with 98-100% mortality at 10 times the diagnostic concentration in five of seven sentinel sites. However, the proportion of survivors at two times the diagnostic concentration of deltamethrin was generally high, with mean mortality of 63% across all sites. The data contradict the findings of WHO susceptibility tests, which showed full susceptibility to deltamethrin in two sites, possible resistance in five sites and resistance to deltamethrin only in Kimpese, Karawa, Pawa and Kalemie.

Full susceptibility was recorded in WHO tests in Inongo and Katana. Conversely, 24% survivors were recorded in Inongo at two times the diagnostic concentration and 20% survivors at five times in Katana.

**Table 3: Resistance intensity of *An. gambiae* s.l. to ×1, ×2, ×5, ×10 the diagnostic concentration of permethrin**

*NB. In each test, 25 An. gambiae s.l. were in an untreated control. Mortality was zero in all.
4.2. Vector Species Composition

4.2.1. Tshopo Province, Kabondo Site (January – June 2017)

Figure 3: Morphological Anopheles species composition captured by PSC and HLC indoors and outdoors in Kabondo

In Kabondo, An. gambiae s.l. was the most common species caught by HLC and PSC throughout the year.

4.2.2. Tanganyika Province, Kalemie Site (January - June 2017)

Figure 4: Distribution of Anopheles captured by PSC and HLC indoors and outdoors in Kalemie
An. gambiae s.l. was the predominant species caught in Kalemie through PSC and HLC.

4.2.3. **Sud Kivu Province, Katana Site (January- June 2017)**

**Figure 5: Distribution of Anopheles captured by PSC and HLC indoors and outdoors in Katana**

In Katana, An. gambiae s.l. and An. funestus s.l. were caught in similar proportions by PSC and HLC outdoors.

4.2.4. **Kinshasa Province, Kingasani Site (January- June 2017)**

**Figure 6: Distribution of Anopheles captured by PSC and HLC indoors and outdoors in Kingasani**
In Kingasani, *An. gambiae* s.l. was the predominant species followed by approximately 15-20% *An. funestus* s.l. collected by PSC and HLC.

**4.2.5. Kasai Province, Mikalayi Site (January- June 2017)**

**Figure 7:** Distribution of *Anopheles* Captured by PSC and HLC indoors and outdoors In Mikalayi

In Mikalayi, *An. funestus* s.l. was the predominant species collected by PSC and HLC both indoors and outdoors.

**NEW SENTINEL SITES FOR 2017 (KARAWA, INONGO, KIMPESE, PAWA)**

**4.2.6. Sud Ubangi Province, Karawa Site (January- June 2017)**

**Figure 8:** Distribution of *Anopheles* Captured by PSC and HLC indoors and outdoors in Karawa
In Karawa, *An. gambiae* s.l. accounted for 99% of *Anopheles* caught by PSC and HLC both indoors and outdoors.

### 4.2.7. Mai-Ndombe Province, Inongo Site (January- June 2017)

**Figure 9: Distribution of Anopheles Captured by PSC and HLC indoors and outdoors in Inongo**

In Inongo, 99% of *Anopheles* PSC collected resting indoors were *An. gambiae* s.l. For HLC indoors and outdoors, around 40% were *An. paludis*. This suggests *An. paludis* rest predominantly outdoors, even after indoor biting.
4.2.8. **Kongo Central Province, Kimpese Site (January-June 2017)**

Figure 10: Distribution of *Anopheles* Captured by PSC and HLC Indoors and Outdoors in Kimpese

In Kimpese, *An. funestus* s.l. was the most abundant species collected by HLC and PSC.

4.2.9. **Haut-Uele Province, Pawa Site (January-June 2017)**

Figure 11: Distribution of *Anopheles* Captured by PSC and HLC indoors and outdoors in Pawa

In Pawa, *An. gambiae* s.l. were most abundant (83%-92%) followed *An. paludis* (8%-16%). The project collected *An. paludis* mostly during the dry season (May-June) (see Annex). Unlike in Inongo, the team captured *An. paludis* resting indoors.

</tbody>
</table>

The mean indoor human biting rate of *An. gambiae* s.l. in 2017 varied between one bite per person per night in Mikalayi and up to 23 bites per person per night in Pawa. The outdoor human biting rate of *An. gambiae* s.l. in 2017...
varied between zero bites per person per night in Katana and up to 32 bites per person per night in Pawa. In general, there was significant outdoor biting potential, with outdoor biting rates similar to indoor biting rates for both *An. gambiae* s.l. and *An. funestus* s.l.

The biting rate of *An. funestus* s.l. was substantial in two sites, with an indoor biting rate of 10 in Mikalayi and 32 bites per person per night in Kimpese. Statistical comparison of biting rates should not be made between regions due to the relatively small number of houses sampled and differences in sampling timing.

### 4.4. Biting Times of Malaria Vectors Indoors and Outdoors

Biting trends are presented only for locations where the total number caught per species by HLC was >200 between January and June 2017. In general, indoor biting by *An. gambiae* s.l. and *An. funestus* s.l. was primarily late at night, between 22:00 and 05:00, and mirrored outdoor biting trends. In Kimpese and Pawa, there was substantial biting occurring between 5:00am and 6:00am; thus, longer monitoring may be useful to determine whether morning biting occurs.

#### 4.4.1. Tshopo Province, Kabondo Site (January – June 2017)

**Figure 12: Mean nightly biting activity of *An. gambiae* s.l. at Kabondo site (January – June 2017), N=456 Indoors, N=347 Outdoors.**

(n refers to total *An. gambiae* collected over the trapping period)
4.4.2. Kasai Province, Mikalayi Site (January – June 2017)

Figure 13: Biting activity of An. funestus s.l. at Mikalayi site (January – June 2017), N=246 Indoors, N=95 Outdoors

(n refers to total An. gambiae collected over the trapping period)

NEW SENTINEL SITES FOR 2017 (KARAWA, KIMPESE, PAWA)

4.4.3. Sud Ubangi Province, Karawa Site (January – June 2017)

Figure 14: Biting activity of An. gambiae s.l. at Karawa site (January – June 2017), N=405 Indoors, N=321 Outdoors

(n refers to total An. gambiae collected over the trapping period)
4.4.4. Kongo Central Province, Kimpese Site (January–June 2017)

Figure 15: Biting activity of *An. funestus* s.l. at Kimpese site (January – June 2017) N=772 Indoors, N=953 Outdoors
(n refers to total *An. gambiae* collected over the trapping period)

4.4.5. Haut-Uele Province, Pawa Site (January–June 2017)

Figure 16: Biting activity of *An. gambiae* s.l. at Pawa site (January – June 2017) N=543 Indoors, N=761 Outdoors
(n refers to total *An. gambiae* collected over the trapping period)
4.5. Monthly Monitoring of Malaria Vectors in Lodja and Kapolowe (January – December 2017)

4.5.1. Biting rate

In Kapolowe, *An. funestus* s.l. was the most abundant malaria vector, with particularly high biting rates at >100 bites per person per night in March and consistently above 20 bites throughout the year.

The peak biting rates for *An. gambiae* s.l. were between January and March (the rainy season). For *An. funestus* s.l., the biting peak was later, between March and May, with biting continuing at relatively high rates throughout the dry season (Figures 17).

In Lodja, *An. gambiae* s.l. was the primary malaria vector collected, with three apparent biting peaks in January, May, and October (Figure 18). *An. paludis* biting was predominantly outdoors and peaked in September with 40 bites per person per night (Figure 18).

Figure 17: Monthly indoor (left) and outdoor (right) biting rate of *Anopheles* species in Kapolowe (Haut Katanga) from HLC collections (8 houses per month)
4.5.2. Biting Times of Anopheles Species Indoors and Outdoors

In Kapolowe, the mean hourly biting rates of An. gambiae s.l. and An. funestus s.l. were fairly constant throughout the night both indoors and outdoors (Figure 19). This is in keeping with trends from 2016.

In Lodja, An. gambiae s.l. biting trends were mirrored indoors and outdoors, with a gradual increase in biting rates until the peak at 1:00, followed by a gradual decrease until dawn (Figure 20).

Figure 19: Nocturnal biting times of An. gambiae s.l. and An. funestus s.l. indoors and outdoors in Kapolowe (Haut Katanga).
Figure 20: Nocturnal biting times of *An. gambiae* s.l. and *An. funestus* s.l. indoors and outdoors in Lodja (Sankuru)

*An. gambiae* s.l (Lodja), January-December, 2017 (n= 1,431 indoor, n= 1,724 outdoor)

*An. funestus* s.l (Lodja), January-December, 2017 (n= 176 indoor, n= 131 outdoor)

Figure 21: Nocturnal biting times of *An. paludis* indoors and outdoors in Lodja (Sankuru)

*An. paludis* (Lodja), January-December 2017

(n= 420 indoor, n= 2,762 outdoor)
4.6. Impact of Resistance on Survival Following Exposure to LLINs

</tbody>
</table>

0% mortality rate was observed in control with untreated net against both susceptible and resistant *An. gambiae* s.l.

WHO susceptibility tests showed that wild *An. gambiae* s.l. from Kingasani were resistant to permethrin and alpha-cypermethrin, with possible resistance to deltamethrin.

All used and new permethrin and deltamethrin LLINs produced mortality rates inferior to the WHO bio-efficacy threshold of 80% mortality at 24h after exposure for both insectary and wild *An. gambiae* s.l. The biggest difference in mortality was for the used Duranet, with mortality at 47% for wild *An. gambiae* s.l. and 100% for *An. gambiae* Kisumu. This appears to indicate that alpha-cypermethrin resistance in Kingasani may affect used LLIN performance.
4.7. Intensity of Pyrethroid Resistance of *An. gambiae* s.l. in Kinshasa

¹Mortality of 98-100% at the 5x concentration; ²Mortality of < 98% at 5x but in the range 98-100% and ³Mortality < 98% at the 5x and 10x.

Permethrin resistance intensity was the same (high) before (2016) and after (2017) the mass LLIN distribution in Kinshasa suburbs. Deltamethrin resistance intensity was the same (moderate) in Kasangulu before (2016) and after (2017) the LLINs distribution. Observed deltamethrin resistance intensity in 2017 was less than that in 2016 in Kimpoko, Kingasani, and Kinkole. The detailed data are in Annex C.
University of Notre Dame received samples morphologically identified as *An. paludis* collected by HLC in 2015, predominantly from Kapolowe. The team dissected a subset of samples (head and thorax from abdomen), extracted DNA using cetyl trimethylammonium bromide, conducted internal transcribed spacer polymerase chain reaction, amplified samples, and conducted Sanger sequencing. Of the *An. paludis* samples tested from Kapolowe, the majority were molecularly identified as being *coustani*-like species (*An. cf coustani* 1 & 2) with the sequences corresponding to those reported from Zambia.

**Figure 22. Molecular species composition in Kapolowe for mosquitoes morphologically identified as *An. paludis*.**

Human landing catch was conducted in Kenge in the Kwango Province to research the presence of *An. paludis*, which was identified as a malaria vector in this region in 1992 (Karch et al). Just one female specimen was captured and identified as *An. paludis*. This specimen was sent to CDC/Atlanta for further analysis. *An. paludis* collected from all sites in 2017 will be sent to the University of Notre Dame for sequencing analysis.
In collaboration with the NMCP, the INRB conducted group training for three supervisors from each of the 11 sites in Kinshasa from July 17 to July 22. The objective was for field supervisors at all sites to be able to conduct insecticide susceptibility testing and morphological species identification in addition to PSC and HLC. The training consisted of theoretical instruction on mosquito morphological identification, mosquito sampling methods, rearing mosquitoes in the laboratory, labelling and conservation of mosquito samples, susceptibility, and CDC bottle resistance intensity testing. INRB conducted practical sessions in the field on HLC, PSC, and larvae collections and in the laboratory by performing WHO susceptibility tests and intensity tests according to standard operation procedures (SOPs) 001/01 and 001/03.

AIRS Entomologist Dr. Rodrigue Fiacre Agossa worked with the INRB team as a trainer. He focused his efforts on capacity building by developing a culture of using SOPs for all activities, improving supervisors’ skills in mosquito identification, improving productivity of the insectary, troubleshooting field data, and working with the laboratory team.

</tr>
</tbody>
</table>
### Activity Purpose Timeline Frequency STATUS

**Vector susceptibility**
- Determine intensity of insecticide resistance
  - July – August 2017
  - 7 sites
  - Completed

**Enzyme-linked immunosorbent assay (ELISA) work**
- To determine the sporozoite rate and calculate the entomological inoculation rate
  - March – October 2017
  - 11 sites
  - Completed for 9 sites. Not yet completed in Kapolowe and Lodja. Scheduled for January and February 2018

**Evaluation of Anopheles paludis as malaria vector**
- Determine whether An. paludis is a vector of malaria in Kenge
  - March 2017
  - 1 site, 1 time
  - Completed; however, only one An. paludis female was captured. It was sent to CDC for analysis

### ANNEX B. Technical Support

<table>
<thead>
<tr>
<th>Scientific support – short-term technical assistance in DRC from Richard Oxborough (AIRS). Technical, financial, and contractual support from Djenam Jacob (AIRS).</th>
<th>The technical team conducted a short-term technical assistance trip in May 2017. The technical team visited field sites in Kimpese where April - June 2017 activities took place. The technical team shared the objectives of the study with the local authorities and gave guidance to supervisors for mosquito species identification and susceptibility testing. The financial team explored the financial network.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Training</td>
<td>INRB and Dr. Agossa, in collaboration with the NMCP, conducted group training for three supervisors from each of the 11 sites in Kinshasa from July 17 to July 22 with financial support from Abt through PMI AIRS. The objective is for field supervisors at all sites to be able to conduct insecticide susceptibility testing and species identification in addition to PSC and HLC.</td>

</table>
The abdominal status of malaria vectors collected by PSC between January and June 2017 is presented in Table 15. In all sites, the majority of An. gambiae s.l. and An. funestus s.l. collected by PSC were blood-fed (24-88%), with <18% being either half-gravid or gravid.

MONTHLY MONITORING OF ABDOMINAL STATUS FOR MALARIA VECTORS CAUGHT RESTING INDOORS BY PSC

In Kapolowe, the majority of captured An. gambiae s.l. and An. funestus s.l. were blood-fed (75%). In Lodja, the majority of An. gambiae s.l. and An. funestus s.l. captured by PSC indoors between January and December were either unfed (32%) or blood-fed (63%), with very few half-gravid (4%) or gravid (1%) females.
